Outgroup morality perceptions mediate secondary transfer effects from direct and extended contact: Evidence from majority and minority group members

Loris Vezzali,1 Gian Antonio Di Bernardo,1 Michèle D. Birtel,2 Sofia Stathi,2 and Marco Brambilla3

Abstract
The secondary transfer effect (STE), defined as contact with a primary outgroup improving attitudes towards a secondary outgroup uninvolved in contact, has mainly been studied with reference to direct contact and considering attitude generalization as the main mediating mechanism. Using a majority (422 Italians) and minority (130 immigrants) adolescent sample from high schools in Italy, we examined outgroup morality perceptions as a new mediating mechanism, and tested for the first time whether the STE emerges for extended contact. Results revealed that the STE emerged for direct contact among the majority group and for extended contact among the minority group, and it was sequentially mediated by perceptions of morality towards the primary outgroup, and by attitudes towards the primary outgroup and perceptions of morality towards the secondary outgroup. The STE also emerged for direct contact among the minority group, with morality perceptions towards the secondary outgroup and attitudes towards the primary outgroup being parallel mediators. We discuss the theoretical implications of the findings, arguing that it is important to identify the conditions and underlying processes of the STE in order to reduce prejudice in the case of both majority and minority groups.

Paper received 16 August 2018; revised version accepted 8 September 2019.

The growing cultural and social diversity in today’s societies raises intergroup concerns and feelings of threat among both majority and minority group members (Chang, Krosch, & Cikara, 2016; Stephan & Stephan, 2000; Travalter, Richeson, & Shelton, 2009). Meaningful contact between members of different groups has been shown to

promote positive intergroup relations (Allport, 1954; Pettigrew & Tropp, 2006). However, not everyone has opportunities for contact with minority groups due to educational and residential segregation (Birtel, Reimer, Wölfer, & Hewstone, 2019), as for example in Northern Ireland and Cyprus. Additionally, even when there are opportunities for intergroup contact, ingroup members tend to avoid contact with outgroup members (Al Ramiah, Schmid, Hewstone, & Floe, 2015; Stephan & Stephan, 1985). Furthermore, intergroup distinctions stem from various characteristics, such as ethnicity and health/disability, and these characteristics can form the basis of stigmatization. With increased immigration (United Nations, Department of Economic and Social Affairs, 2015) and disability rates (World Health Organization [WHO], 2018), we need to understand how to effectively reduce prejudice towards different types of stigmatized groups.

Research has consistently shown that direct contact is not necessary for prejudice reduction, and that the potential of contact can also emerge when contact is indirect, that is, when it is not face-to-face. Previous research has demonstrated the positive effects of indirect forms of contact on intergroup relations, such as extended contact (i.e., knowing that ingroup members have outgroup friends; Birtel, Vezzali, & Stathi, 2018; Vezzali, Hewstone, Capozza, Giovannini, & Wölfer, 2014; Wright, Aron, McLaughlin-Volpe, & Ropp, 1997; Zhou, Page-Gould, Aron, Moyer, & Hewstone, 2018). But the potential of contact, and specifically the potential that contact has to reduce prejudice, can also be realized through generalization processes, and specifically through generalization from the outgroup one has contact with (primary outgroup) to an uninvolved outgroup (secondary outgroup); this phenomenon is called secondary transfer effect (STE; Pettigrew, 1998, 2009).

Adding to the potential for extended contact to reduce prejudice, and for the STE to extend these benefits to groups uninvolved in direct or indirect (i.e., extended) contact, the present research considers three key gaps in the literature. Firstly, while there are studies showing the STE for direct contact (for a review, see Lolliot et al., 2013), research that combines indirect (i.e., extended) contact with the benefits provided by the STE is surprisingly scarce. In addition to contributing to this scarce literature, we test for the first time whether the STE manifests for extended contact, and we examine this for both majority and minority group members. Secondly, research has mainly focused on attitudes as the main explanation for the STE (for a review, see Lolliot et al., 2013), but also on intergroup emotions (Giovannini & Vezzali, 2011; Vezzali & Giovannini, 2012) and individual differences (Shook, Opkins, & Koech, 2016; Vezzali et al., 2018). It has, however, neglected variables strongly related to impression formation like morality perceptions (Brambilla & Leach, 2014). In examining morality perceptions, we also address a relevant gap in the contact literature, which only recently has started to test outgroup morality as a mediator of contact effects (Brambilla, Hewstone, & Colucci, 2013). Thirdly, in order to achieve a long-lasting change in relations between ingroup and outgroup members, behavioral variables, or relevant behavioral proxies, need to be taken into account as outcome variables in addition to attitudes.

In the present article, we tested the STE in an ethnic majority and minority adolescent sample in Italy. We examined whether contact improves attitudes and contact intentions between Italians and immigrants, and whether these positive effects generalize to a secondary, dissimilar outgroup, that is, disabled people (STE). In order to address the aforementioned gaps in the literature, we examined the independent STEs for both direct and extended contact. Furthermore, we tested a new mediator, outgroup morality perceptions. Importantly, to consider more proximal behavioral outcomes, we measured intentions to engage in contact with the secondary outgroup. We are currently not aware of other studies testing contact intentions as the outcome of the STE. With this study, we provide a significant contribution to understanding the potential of direct and extended contact to reduce prejudice towards primary and secondary outgroups, as well as the processes that explain this.
The Secondary Transfer Effect of Intergroup Contact

There is impressive evidence for Allport’s (1954) intergroup contact theory, showing that positive contact with outgroup members reduces prejudice (Pettigrew & Tropp, 2006; Vezzali & Stathi, 2017). Generalization processes facilitate contact effects (Pettigrew, 1997, 1998, 2009). In his seminal work, Pettigrew (1998) outlines three types of generalization of contact effects: from the outgroup member to the outgroup as a whole, across contact situations, and to outgroups not involved in the initial contact situation (i.e., STE; Pettigrew, 2009; for a review, see Lolliot et al., 2013). Despite the powerful effects of contact on intergroup relations, studies have mainly focused on the first two types of generalization, and there has been relatively limited research on the STE. We note, however, that in recent years a consistent body of evidence documented the existence of the STE (e.g., Brylka, Jasinskaja-Lahti, & Mahonen, 2016; Lissitsa & Kushnirovich, 2018; Mahonen & Jasinskaja-Lahti, 2016; Meleady & Forder, 2018; Schmid, Hewstone, Kupper, Zick, & Wagner, 2012; Schmid, Hewstone, & Tausch, 2013; Shook et al., 2016; Tausch et al., 2010; Vezzali et al., 2018). Although research so far has provided convincing evidence for the STE, there is a need to examine relevant underlying processes, whether it occurs both for majority and minority group members alike, and whether indirect forms of contact, such as extended contact, can also produce it.

Extended Contact and the Secondary Transfer Effect

Indirect forms of contact, such as knowing that an ingroup member is friends with an outgroup member (extended contact), observing an intergroup interaction (vicarious contact; Vezzali et al., 2014; Zhou et al., 2018), or imagining positive contact (Crisp & Turner, 2012; Miles & Crisp, 2014) are effective means of improving intergroup relations. While most of the research has examined the STE in the context of direct contact (Lolliot et al., 2013), there is some evidence for its existence in the case of vicarious (Joyce & Harwood, 2014) and imagined contact too (De Carvalho-Freitas & Stathi, 2017; Harwood, Paolini, Joyce, Rubin, & Arroyo, 2011; Visintin, Birtel, & Crisp, 2017). However, research has not yet examined if extended contact can lead to the STE. Schmid et al. (2012) included a measure of extended contact but used a combined measure of direct and extended contact to analyze the STE, therefore it is not possible to disentangle the effects of direct from those of extended contact.

Our first aim was to test whether extended contact generalizes to secondary outgroups among majority and minority group members. While direct contact effects tend to be less strong for minority (effect size \( r = -0.18 \)) than majority (effect size \( r = -0.23 \)) group members (Tropp & Pettigrew, 2005), extended contact effects do not appear to differ significantly in their effect size between majority (\( r = 0.23 \)) and minority (\( r = 0.22 \)) group members (Zhou et al., 2018). In line with these meta-analytic results, the STE was found for the majority group’s contact with the minority, but not for the minority group’s contact with the majority (van Laar, Levin, Sinclair, & Sidanius, 2005; Vezzali et al., 2018). In our study, we examined the STE for both majority and minority group members by considering different types of contact; we predicted to find the STE for direct contact among majority group members, and for extended contact among both groups.

According to research findings, the STE tends to be stronger for secondary outgroups that are similar to the primary outgroup (Harwood et al., 2011; Joyce & Harwood, 2014), but also occurs for dissimilar outgroups (e.g., Schmid et al., 2012, ethnicity to sexual orientation; Tausch et al., 2010, religion to ethnicity). In our study, we tested whether the STE manifests for dissimilar groups, generalizing from positive attitudes towards a different ethnic group to people with disability (see also Vezzali et al., 2018). Going a step further, we tested whether this generalization occurs not only for direct but also for extended contact.
## Processes Underlying the Secondary Transfer Effect

Research has generally focused on outgroup attitudes as the main mediator of the STE, that is, contact with the primary outgroup is associated with more positive attitudes towards the secondary outgroup, mediated by positive attitudes towards the primary outgroup (Brylka et al., 2016; Pettigrew, 2009; Schmid et al., 2012; Schmid et al., 2013; Tausch et al., 2010; Vezzali & Giovannini, 2012).

For example, Tausch et al. (2010) demonstrated in three cross-sectional studies (Cyprus, Northern Ireland, Texas) and one longitudinal study (Northern Ireland), with overall 4,312 participants, that contact with the primary outgroup is associated with reduced prejudice towards a secondary outgroup via more positive attitudes towards the primary outgroup. Furthermore, Vezzali and colleagues showed that the STE, via attitude generalization, also occurs among adolescents (Vezzali & Giovannini, 2012) and even among elementary school children (Vezzali et al., 2018) from the ethnic majority (but not minority) group.

While the basic attitude generalization effect of contact is now established, not much is yet known about additional underlying processes of the STE. Recent research indicates that processes other than attitude generalization may play a role. For example, intergroup emotions, which are the key mediators of the contact–prejudice relationship (e.g., intergroup anxiety and empathy; Pettigrew & Tropp, 2008), can also explain the generalization of positive attitudes to secondary outgroups (Giovannini & Vezzali, 2011; Vezzali & Giovannini, 2012). Additionally, there is some evidence that the STE can be explained by individual differences such as social dominance orientation (Shook et al., 2016; Vezzali et al., 2018).

Evidence considering other mediators, such as ingroup identification, is mixed (Pettigrew, 2009; Schmid et al., 2013). Therefore, there is a need to understand the processes of the STE beyond the mediating role of intergroup attitudes. As such, we argue that perceptions regarding the morality of the outgroup could play an important role in explaining the positive effect of contact on secondary outgroups.

## Outgroup Morality Perceptions as a Mediator of Contact Effects

Morality refers to principles and values that indicate whether a behavior towards others is right or wrong, and it drives interpersonal and intergroup perceptions (Brambilla & Leach, 2014). Morality influences how people feel about themselves (Rodriguez Mosquera, Manstead, & Fischer, 2002) and how they act (Schwartz, 1992). When evaluating others based on their perceived traits, various dimensions such as sociability, morality, and competence can be considered. While sociability refers to the ease of forming a connection with others (e.g., friendliness), morality informs how (un)trustworthy or threatening someone is (Brambilla, Biella, & Freeman, 2018; Leach, Ellemers, & Barreto, 2007).

Research has shown that morality drives person and group impression formation (Brambilla & Leach, 2014). For example, Brambilla, Rusconi, Sacchi, and Cherubini (2011) found that, when forming impressions of others, people have a greater tendency to gather information about the morality rather than the sociability or competence of a social target, as morality is highly informative of others’ intentions. In a similar vein, moral information is more critical than information about sociability or competence in determining the overall impression that people form of other individuals and groups (Brambilla, Sacchi, Rusconi, Cherubini, & Yzerbyt, 2012). Importantly, morality not only affects impression formation, but also interpersonal (Brambilla, Sacchi, Menegatti, & Moscatelli, 2016) and intergroup behavior (Brambilla, Sacchi, Pagliaro, & Ellemers, 2013). As such, Brambilla, Sacchi, et al. (2013) manipulated moral qualities of ingroup and outgroup targets. In general, participants reported lower intentions to interact with targets that were perceived as lower in moral traits, which was mediated by perceived threat. For ingroup members, the immoral target was perceived as a threat to the ingroup image, for outgroup members the target was perceived as a
threat to the ingroup’s safety. Moreover, impressions are more polarized when individuals evaluate others’ morality rather than other characteristics (Brambilla, Carraro, Castelli, & Sacchi, 2019). Taken together, these studies show that morality perceptions are important predictors of interpersonal and intergroup attitudes (Brambilla & Leach, 2014).

Despite its importance in regulating interpersonal and intergroup interactions, outgroup morality has been overlooked in intergroup contact research as a potential mediator of the contact effects, with the exception of two studies that examined attitudes towards minority group members. Brambilla, Hewstone, et al. (2013) found that Italians’ contact with immigrants was associated with greater perceptions of immigrants as competent, sociable, and moral, as well as with greater intentions to support actions for social change. Importantly, only outgroup morality mediated the effect of contact on social change intentions. Vezzali, Brambilla, Giovannini, and Colucci (2017) found that direct and extended cross-group friendships of Italian high school students with gay people were associated with greater intentions to interact with gay people. This effect of contact on sexual prejudice was mediated by a component of morality, and specifically by higher perceived moral purity of gay people. Extending these studies, we tested whether outgroup morality mediates the effect of direct and extended contact on intergroup attitudes and behavioral intentions among both majority and minority group members, and whether outgroup morality also explains the STE.

Based on the reviewed literature, which shows that morality perceptions drive the formation of attitudes, including intergroup attitudes, and mediate contact effects, we predict that perceived morality of the primary outgroup will mediate the effects of (direct and extended) contact on attitudes towards the primary outgroup, and in turn, on attitudes towards the secondary outgroup.

In addition, we predict that perceived morality of the primary outgroup will mediate the contact effects on perceived morality of the secondary outgroup, and in turn on attitudes towards the secondary outgroup. As reported in the previous lines, prior research has shown that outgroup morality has a powerful role in predicting intergroup impressions and attitudes (Brambilla et al., 2012). In a similar vein, the perception that an outgroup is moral might generalize to a secondary outgroup (that shares the characteristic of stigmatization with the primary outgroup) because of an enhanced perception that intergroup relations are generally governed by shared moral values. In other words, intergroup contact can increase the attribution of morality to the outgroup, and at the same time enhance the perception that groups with distinct identities can also be moral. This, consequently, facilitates the attribution of morality to secondary outgroups, and in turn more positive attitudes towards them.

**The Present Research**

In the present study we sought to examine whether intergroup contact experiences between ethnic majority (Italian) and minority (immigrant) adolescents generalize to attitudes towards a secondary, dissimilar but also stigmatized outgroup (i.e., disabled people). The model we tested is depicted in Figure 1.

We argue that our study is novel in three ways. Firstly, in relation to the STE, we not only considered direct contact (i.e., cross-group friendships) in line with previous research, but also extended contact for both ethnic majority and minority group members. Only one previous study (Schmid et al., 2012) considered extended contact and the STE; however, extended contact was combined with direct contact into one measure, and thus the unique effect of extended contact was not tested.

Secondly, in addition to intergroup attitudes (to be consistent with past literature), we tested a new mediator of the contact–attitudes relationship, outgroup morality perceptions, for both the primary and the secondary outgroup.

Thirdly, in addition to attitudes towards the secondary outgroup (which represents a classic dependent variable in the STE research), since intention is a more proximal predictor of behavior
than attitudes (Fishbein & Ajzen, 1974), we measured intentions to have contact with the secondary outgroup as an outcome variable. This way, our study tested the generalization of contact effects on a variable that is more proximal to behavior and its underlying processes.

We made the following predictions:

H1: The STE should emerge among majority members as an outcome of direct contact, and among both majority and minority members as an outcome of extended contact.

H2: Effects of direct (for the majority group members only) and extended contact on attitudes and contact intentions towards the secondary outgroup should be sequentially mediated by increased perceptions of morality towards the primary outgroup (first level mediator), and by improved attitudes towards the primary outgroup and morality of the secondary outgroup (second level mediators; Figure 1).

To be conservative, we controlled for direct and extended contact with the secondary outgroup to rule out the possibility that effects could be explained at least in part by the fact that individuals with more contact with the primary outgroup also have more contact with the secondary outgroup (Schmid et al., 2013; Vezzali & Giovannini, 2012).

Method

Participants and Procedure

Five hundred and fifty-eight students from seven high schools located in Northern Italy took part in the research. Individuals with intellectual disabilities, as indicated by teachers, were excluded from the administration of the questionnaire as they might have encountered difficulties in completing it. Six immigrant participants were excluded from the analysis because of high levels of missing data (> 20%). Thus, the final sample consisted of 552 respondents, namely 422 Italians (225 males, 197 females; $M_{age} = 17.20, SD = 1.10$) and 130 immigrants (55 males, 75 females; $M_{age} = 17.61, SD = 1.42$). The distinction between Italians and immigrants was made on the basis of school indications, taking into account whether children
had parents of foreign (i.e., non-Italian) origin. 
Regarding the origin of the immigrant sample, the most represented birth continents were Asia (36.2%), followed by Africa (31.5%) and Eastern Europe (25.4%).

The sample size for the majority group (i.e., Italians) allowed reaching a power for conducting a mediation analysis of at least 0.8 to detect a small effect size (Fritz & MacKinnon, 2007). The smaller sample size of the minority group (i.e., immigrants) instead allowed reaching a power of 0.75 to detect a small effect size.

Participants completed a questionnaire that was distributed during class hours. In the Italian version, the primary outgroup target was immigrants; in the version for immigrants, Italians were the primary outgroup. All participants completed the questionnaire in the Italian language.

Measures

Direct contact with the primary and the secondary outgroup. Five items considering students’ cross-group friendships, an especially powerful form of contact (Davies, Tropp, Aron, Pettigrew, & Wright, 2011; Turner, Hewstone, Voci, Paolini, & Christ, 2007), were used for assessing direct contact of the ingroup with the primary and the secondary outgroup. In particular, participants were asked how many primary and secondary outgroup friends they have (1 = none, 5 = a lot), and how many friends they have among immigrants/Italians and among individuals with disabilities (a) in general, (b) at school, (c) in the neighborhood, and (d) during free time (1 = none, 2 = from 1 to 2 friends, 3 = from 3 to 4 friends, 4 = from 5 to 6 friends, and 5 = more than 6 friends). Items were combined to form reliable measures of direct contact with primary or secondary outgroup members (α = .88 and .73 for primary and secondary outgroup, respectively).

Extended contact with the primary and the secondary outgroup. Five parallel items were created for assessing extended contact. Similar to the direct measure, participants were asked to indicate how many of their friends had an immigrant/Italian or an individual with disability as friend, in general (two items), at school, in the neighborhood, and during free time (see Lolliot et al., 2015; Tausch, Hewstone, Schmid, Hughes, & Cairns, 2011; Turner, Hewstone, Voci, & Vonofakou, 2008). Response scales were identical to the aforementioned direct friendship items. We averaged items to obtain indices of extended contact with primary (α = .90) and secondary (α = .85) outgroups.

Morality of the primary and the secondary outgroup. Primary and secondary outgroup perceptions of morality were measured using three items taken from Brambilla, Hewstone, et al. (2013). In particular, participants were asked to rate how much they perceived the outgroups as “honest,” “trustworthy,” and “sincere” on a 5-point scale (1 = not at all, 5 = very much). We obtained indices of morality towards primary (α = .91) and secondary (α = .91) outgroups by averaging respective items.

Attitudes towards the primary and the secondary outgroup. A feeling thermometer was employed in order to evaluate both the primary and the secondary outgroups (based on Haddock, Zanna, & Esses, 1993). Specifically, respondents indicated, on a graphic thermometer, their attitudes towards immigrants/Italians and towards individuals with disability (0 = extremely negative, 100 = extremely positive, 50 = neither positive, nor negative [as the neutral point]).

Contact intentions towards the secondary outgroup. Three items measuring contact intentions adapted from Mackie, Devos, and Smith (2000; see also Turner, West, & Christie, 2013) were used. Participants were asked to think about the next time they would meet a person with disability and to rate how likely they would be to (a) start a conversation, (b) be interested in starting a conversation, and (c) wish to start a conversation (1 = not at all, 5 = very much). Items were averaged in a single index of contact intentions towards the secondary outgroup (α = .91).
Results

Descriptive statistics and correlations for Italians and immigrants are presented in Table 1 and Table 2, respectively. Overall, minority members had more outgroup friends than majority members, both with respect to direct and extended contact; conversely, majority members had more friends among the secondary outgroup than minority members, but no differences emerged regarding extended contact. Regarding morality, minority members perceived the outgroup as more moral compared with majority individuals; on average, secondary outgroup members were rated more moral by the majority than by the minority sample. Concerning attitudes towards the primary outgroup, the minority rated the outgroup more positively than the majority; in any case, attitudes towards the primary outgroup were positive for both samples since means are significantly different from the neutral point of the scale ($t(550) > 5.94$, $p < .001$). No differences emerged regarding contact intentions towards the secondary outgroup.

Hypotheses were tested by employing structural equation models with LISREL 8.8 (Jöreskog & Sörbom, 2007). In particular, contact measures (direct and extended contact with the primary outgroup) represented the exogenous variables; morality ascribed to the primary outgroup represented the first level mediator; attitudes towards the primary outgroup, along with morality of the secondary outgroup, were the second level mediators; contact intentions and attitudes towards the secondary outgroup were the dependent variables. The direct paths from direct and extended contact to second level mediators and to dependent variables were estimated. Direct and extended contact with the secondary outgroup and gender were included as covariates in the model, that is, all the paths from the covariates to mediators and dependent variables were estimated.

Model fit evaluation was assessed by employing the indexes suggested by Hu and Bentler (1999; see also Kline, 1998). Specifically, a $\chi^2/df$ lower than 3, a CFI greater than .95, a SRMR equal or smaller than .08, and a RMSEA equal or smaller than .06, indicate a good fit. Significance of the indirect effects was tested by using bootstrapping procedures with 5,000 resamples.

Majority Sample

For the majority sample, a structural equation model with latent variables was applied (Table 3, Figure 2). For each latent construct two indicators

were created following the indications by Little, Cunningham, Shahar, and Widaman (2002), with the exception of the attitude towards primary and secondary outgroup measures that were composed of single items. In this latter case, the corresponding latent factor loaded on a single indicator with the relative error fixed to zero. Direct and extended contact with the secondary outgroup and gender were controlled for (morality, attitudes, and contact intentions towards the secondary outgroup were regressed onto both direct and extended contact with the secondary outgroup).

The proposed model presented a good fit to the data, $\chi^2(81) = 136.75, p < .001, \chi^2/df = 1.69$, RMSEA = .04, CFI = 0.99, SRMR = .03. As can be seen in Figure 2, direct contact was associated with both morality and attitudes towards the primary outgroup. Morality of the primary outgroup was in turn positively related to attitudes towards the primary outgroup and to morality ascribed to the secondary outgroup. Finally, both attitudes towards the primary outgroup and morality of the secondary outgroup were positively associated with increased contact intentions and with more favorable attitudes towards the secondary outgroup.

Table 4 reports the results of the bootstrapping analyses. Direct contact with the primary outgroup was positively associated with contact intentions and attitudes towards the secondary outgroup through the indirect effect of enhanced morality of the primary outgroup and, in turn, attitudes towards the primary outgroup and morality of the secondary outgroup. These findings partially support H1 (effects did not emerge for extended contact) and are consistent with H2.

In addition to the hypothesized model, we tested one plausible alternative model. The first level mediators were morality of the primary outgroup and attitudes towards the primary outgroup, while the dependent variables were morality of the secondary outgroup, contact intentions, and attitudes towards the secondary outgroup. In fact, it is
possible that morality of the primary outgroup and attitudes towards the primary outgroup work as parallel mediators. The model showed a good fit to data, although not as good as that of our proposed model, $\chi^2(82) = 227.79$, $p < .001$, $\chi^2/df = 2.78$, RMSEA = .06, CFI = .97, SRMR = .03. To compare our proposed model with this first alternative model, we used Akaike’s (1987) information criterion (AIC) index, where lower scores indicate better fit. Specifically, we obtained $AIC = 277.27$ for our proposed model, versus $AIC = 360.21$ for this alternative model.
The same model illustrated in Figure 1 was tested with the immigrant sample. In line with the analysis performed for the majority sample, direct and extended contact with the secondary outgroup and gender were controlled for. Due to the lower number of participants, structural equation modelling was applied with observed variables.

Goodness-of-fit indexes showed an excellent fit, $\chi^2(4) = 3.76, p = .44, \chi^2/df = 0.94$, RMSEA $\approx .00, CFI = 1.00, SRMR = .02$. From Table 5 and Figure 3, it emerges that direct contact with the primary outgroup was positively associated with attitudes towards the primary outgroup and with morality of the secondary outgroup. Extended contact with the primary outgroup was positively associated with morality of the primary outgroup; in turn, this variable was positively associated with attitudes towards the primary outgroup and morality of the secondary outgroup. Finally, morality of the secondary outgroup was positively associated with both contact intentions and attitudes towards the secondary outgroup.

Inspection of indirect effects (see Table 6) reveals that, consistent with H1, both direct and extended contact effects generalize to the secondary outgroup. In addition, partially in line with H2, the effects of extended contact are sequentially mediated by perceptions of morality of the primary outgroup, and attitudes towards the primary outgroup and morality of the secondary outgroup. In addition, the effects of direct contact generalize both via morality perceptions and intergroup attitudes.

To rule out alternative explanations, we tested the same alternative model as in the case of the majority sample. Fit indices were almost acceptable, $\chi^2(5) = 15.25, p < .01, \chi^2/df = 3.05$, RMSEA = .12, CFI = .98, SRMR = .04. AIC of the alternative model was higher (113.88) than that of the hypothesized model (105.71), suggesting the better fit of the latter compared to the former.
Discussion

The present research aimed at examining whether (a) the STE emerges as an outcome not only of direct but also of extended contact, (b) the STE emerges among both majority and minority group members, (c) outgroup morality perceptions are an underlying mechanism of the STE, in addition to attitude generalization. We also tested for the first time whether the STE occurs for behavioral intentions towards the secondary outgroup, in addition to attitudes towards the secondary outgroup. Importantly, we provided a stringent test of the STE, by considering dissimilar primary (based on ethnicity) and secondary (based on disability) outgroups, and by controlling for contact with the secondary outgroup.

Extending previous studies demonstrating the emergence of the STE for direct contact among majority groups (van Laar et al., 2005; Vezzali et al., 2018) and high-status minority groups (Brylka et al., 2016), in our study the STE emerged as an outcome of direct contact both for the majority and the minority samples. In line with literature on the STE (Lolliot et al., 2013), results replicated evidence of the effect via attitude generalization. These findings are partly in contrast with our prediction that the STE would not emerge for direct contact in the case of the minority group, based on literature showing that contact is more effective for majority than for minority group members (Tropp & Pettigrew, 2005). However, this unexpected finding can be explained at least in part by the fact that, although less effective, contact in many cases is also effective for the minority group (see Tropp & Pettigrew, 2005). In addition, it should be noted that we focused on an especially effective form of direct contact, that is, direct cross-group friendships (Davies et al., 2011), which may explain why the STE emerged also among the minority group.

For the first time in the literature, we show that the STE also emerges as an outcome of extended contact. Notably, this effect was found among minority group members. This finding is in line with literature showing that extended contact is also effective among minority groups (Vezzali et al., 2014; Zhou et al., 2018), and demonstrates the potential of extended contact to reduce prejudice among individuals from disadvantaged
groups. Unexpectedly, extended contact did not allow the emergence of the STE for the majority group. This may be explained by the fact that majority members relied more on their actual, direct experiences with the minority group. Note that the correlation between direct and extended contact was rather high. In fact, the correlation for the two variables was .69, much higher than the average correlation between direct and extended contact (.46; see Zhou et al., 2018)—considering that the effects of direct contact are generally stronger than those of extended contact (Christ et al., 2010), the high correlation between the two variables may have prevented the emergence of the STE effects for extended contact among majority group members. A complementary explanation may be that the effects of extended contact for the majority group are mediated by variables not

included in the present study: note in fact that, in line with the STE, extended contact was correlated with morality of the secondary outgroup and with contact intentions towards the secondary outgroup among majority group members. Supportive of the STE for extended contact and of the greater role of direct contact, results of an additional model where extended contact was tested among majority group members as a unique independent variable (therefore excluding direct contact) revealed evidence of the STE, mediated by the hypothesized mediators (see Figure 1).3

Replicating scarce evidence on direct (Brambilla, Hewstone, et al., 2013; Vezzali et al., 2017) and extended contact (Vezzali et al., 2017), effects of both contact forms on outgroup attitudes (towards the primary outgroup) were mediated by outgroup morality perceptions. More relevant to the present research, direct and extended contact effects were mediated primarily by morality perceptions of the primary outgroup, and in turn morality perceptions of the secondary and attitudes towards the primary outgroup. It is possible, therefore, that perceived morality of the primary outgroup following contact helps to form an impression of this outgroup and contributes to shaping morality perceptions of uninvolved outgroups. Probably, the latter association is favored by some degree of similarity between the two outgroups (e.g., in terms of a superordinate identity as stigmatized groups) that allows the association between morality perceptions. Future research can include a similarity measure to empirically test this possibility. An important aspect of our study, contributing to research on the STE, was the consideration, for the first time, of behavioral intentions as a measure to assess generalization to the secondary outgroup. Further expanding literature, we found that the STE also emerged for behavioral intentions, and specifically for intentions to have contact with the secondary outgroup. To the extent that intentions are the most proximal predictor of actual behavior (Fishbein & Ajzen, 1974), and that contact intentions lead to formation of cross-group friendships over time (Vezzali, Stathi, Giovannini, Capozza, & Visintin, 2015), we believe these findings are encouraging. We also acknowledge some limitations in the present study. First, results are based on correlational evidence, as is the case with much of the STE literature. However, although this is the first study to test outgroup morality perceptions as the mediating mechanism for the STE, the prediction and findings are in line with previous cross-sectional evidence on outgroup morality as a mediator of contact effects (Brambilla, Hewstone, et al., 2013; Vezzali et al., 2017), as well as with longitudinal (Eller & Abrams, 2004; Tausch et al., 2010; van Laar et al., 2005) and experimental (Shook et al., 2016) evidence. In order to better understand the underlying psychological processes of the STE, future research needs to examine the independent STEs for direct and extended contact in longitudinal and experimental studies. Second, the effects obtained may be specific to the groups we considered and cannot necessarily generalize to other intergroup contexts. Such generalization remains to be tested. Additionally, the sample size of minority group participants was rather small. This limits the interpretation and generalization of these findings to other contexts. Therefore,
we acknowledge that it is important to replicate these findings with larger samples. As an additional point, in our research we relied on the information provided by the school regarding which participants were of immigrant origin. We did not assess whether immigrant participants self-identified as Italians and did not take into consideration the length of their stay in Italy. This may pose a limitation as acculturation variables and self-perceptions can, to an extent, influence immigrants’ attitudes (Zick, Wagner, van Dick, & Petzel, 2002). Therefore, future research can explore the perspective of immigrant groups more thoroughly. Finally, attitudes towards primary and secondary outgroups were assessed with a similar scale. Although we are confident of the validity of our results having acquired similar findings with the other outcome variable (contact intentions towards the secondary outgroup), future studies should nonetheless use different measures to reduce the risk of shared method variance.

Conclusion

In this study we showed that the secondary transfer effect not only emerges for majority group members as an outcome of direct contact but also for minority group members, for both direct and extended contact. Furthermore, perceptions of outgroup morality are a mechanism driving STE, operating in association with intergroup attitudes. Understanding the mechanisms and boundaries of the STE in both majority and minority groups will inform educators and practitioners about the design of interventions that target the growing diversity in today’s society, across categories such as ethnicity, religion, sexual orientation, and health, in order to promote tolerance and positive attitudes.
